United States Population Projection by Marital Status for OASDI Cost Estimates, 1980

Actuarial Study No. 84
by John C. Wilkin, F.S.A.

Preface

The principal purpose of the projection presented in this study is to aid in the preparation of OASDI cost estimates by producing reasonable estimates of the distribution of the projected population by marital status. Although incidence rates of marriage and divorce were not projected to change through time, the effect upon the incidence of marriage resulting from the changing age-sex composition of the unmarried population was reflected. Hence, the projection is a plausible representation of the emerging prevalence of marriage and divorce.

In its Current Population Reports, Series P-25, the Bureau of the Census frequently makes 15 to 20 year projections of the Number of Households and Families based on projected prevalence rates of being single and of being ever married. Although the incidence rate approach used in the preparation of this study still needs refinement in certain areas, we felt that it is an improvement over the prevalence rate approach, and we saw no reason to withhold the work from the public domain. We are currently exploring areas of possible improvements and will gladly welcome comments which may help us further.

Chief Actuary

TABLE OF CONTENTS

A. Basic Concepts

This study presents the population projection by marital status used for
the analysis of potential future financial commitments of the Old-Age
and Survivors Insurance and the Disability Insurance Trust Funds appearing
the the 1980 Report of the Board of Trustees. Although a separate projection
of the population by marital status was prepared for each of the three
alternative sets of assumptions used in the 1980 Trustees Report, only the
alternative II projection is shown here, because of space limitations, and
because the assumptions about changes in marital status were the same for all
three alternatives. The projection presented in this study is consistent
with the Alternative II population projection presented in Actuarial
Study No. 82: United States Population Projections for OASDI Cost Estimates,
1980 by Francisco R. Bayo and Joseph F. Faber, although not all of the numbers
are identical because of rounding.

This population projection by marital status was developed from an estimate
of the current population by marital status and from assumptions about how
that population will change from year to year. The current population by
age, sex, and marital status was derived from Bureau of the Census estimates
of the residents of the 50 states and D.C. (including armed forces overseas),
adjusted for net census undercount and for persons outside of the 50 states
and D.C. who are covered by Social Security, and from data on marital status
in the Current Population Survey. Actuarial Study No. 82 presents an analy-
sis of the change in population by age and sex from year to year by three
components: births, deaths, and net migration. Because assumptions about
these components of change are discussed in detail in Actuarial Study No. 82,
they will be mentioned only briefly in this study. This study further analyzes
the change in the population into marriages, divorces, and widowhoods.[1] Data
on marriages and divorces were obtained from the National Center for Health
Statistics (NCHS). Estimates of widowhoods were based on probabilities of
death for married persons which were derived from the probabilities of death
for the general population discussed in Actuarial Study No. 82.

The marriage statistics available from NCHS refer to marriage rates per 1,000
total population, per 1,000 unmarried women 15 years of age or over, and per
1,000 unmarried women 15-44 years of age. The divorce statistics available
refer to divorce rates per 1,000 total population and per 1,000 married
women 15 years of age or over. These are all gross rates, which have drawbacks
when used for projection purposes.

A good projection procedure will start with a time series of historical data
for each component of change. These data should then be normalized--i.e.,
adjusted to reflect the major characteristics of the past which may have
influenced the data, thereby masking any underlying trend. The analysis of
past trends and the projection of future trends are based on the normalized
data. After the normalized data have been projected, they must be "unnormal-
zied"--i.e., adjusted to reflect the expected major characteristics of the
future which may influence the trend. The analysis of trends is further
simplified if the data on each component of change can be represented by a
single statistic.

---

[1] In this study the number of widowhoods is the number of married persons who
survive the year and who lost their spouse as a result of death during the
year.

Marriage and divorce are the components of change analyzed in this study. The major characteristics of the population which affect the number of marriages and divorces are the size of the population and the age-sex-marital status composition of the population.

Unfortunately, for several reasons the statistics customarily developed from marriage and divorce data are not adjusted to reflect all of these character-istics of the population. For one reason, highly reliable data on marriages and divorces are difficult to obtain and then to match with accurate estimates of the population in which they occurred. Also because marriages and divorces generally involve males and females of different ages, an array of rates must be developed by age of male crossed with age of female. If these rates could be normalized to reflect the age-sex-marital status composition of the popu-lation, and if these rates could be reduced to a single statistic, the projection of trends would become easier.

Robert Schoen has recently developed the concept of rectangular marriage rates, which is the normalization procedure used in this study.[2] Although the con-cept of rectangular marriage rates was developed by Schoen to estimate the marriages between never married persons in a stationary population, in this study the concept is used to estimate total marriages in a projected population. Schoen's concept could be generalized further to derive rectangular divorce rates, although that was not done in this study, partly because of the lack of data. The age of male by age of female specific rectangular rates can be summed to produce a single statistic that does not vary with the age-sex-marital status composition of the population. Unfortunately, no time series of this statistic has been developed from which trends can be analyzed. This study, therefore, does not project the rectangular rates, but rather assumed that they remain constant.

The procedure for using rectangular marriage rates is as follows: first, observed rates are developed from historical data; second, the rectangular rates are calculated by normalizing the observed rates to reflect the compos-ition of the observed population; and third, for each year in the projection period the rectangular rates are adjusted to reflect the composition of the projected population.

The observed rates are:

$$ {}^m a_{ij} = \frac{{}_o n_{ij}}{{}_o^m u_i} \quad , \qquad {}^f a_{ij} = \frac{{}_o n_{ij}}{{}_o^f u_j} $$

where

$\quad {}^m a_{ij}$ = the observed marriage rate for a male aged i marrying a female aged j

$\quad {}^f a_{ij}$ = the observed marriage rate for a female aged j marrying a male aged i

$\quad {}_o n_{ij}$ = the number of observed marriages between a male aged i and a female aged j

2/ Robert Schoen, "A Two-Sex Nuptiality-Mortality Life Table, "Demography, Volume 14, Number 3, August 1977

$^m_o u_i$ = the number of unmarried males aged i in the observed population

$^f_o u_j$ = the number of unmarried females aged j in the observed population

The following formula is used to calculate the rectangular marriage rate b_{ij} from the observed rates.

$$b_{ij} = {}^m a_{ij} \; \frac{\sum\limits_x {}^m_o u_x \, b_{xj} + \sum\limits_y {}^f_o u_y \, b_{iy}}{{}^f_o u_j \left(\sum\limits_x b_{xj} + \sum\limits_y b_{iy} \right)}$$

where b_{ij} = the rectangular marriage rate for a male aged i marrying a female aged j

This equation is solved for b_{ij} iteratively with starting values of:

$$b_{ij} = 1/2 \; ({}^m a_{ij} + {}^f a_{ij})$$

A rectangular population is defined as a population with equal numbers of persons at every age and for both sexes. Rectangular marriage rates can be described as the rates which would be experienced by a rectangular population of unmarried persons.

The adjustment of the rectangular rates to reflect the composition of the projected population can be written as follows:

$$^m c_{ij} = b_{ij} \; \frac{{}^f_p u_j \left(\sum\limits_x b_{xj} + \sum\limits_y b_{iy} \right)}{\sum\limits_x {}^m_p u_x b_{xj} + \sum\limits_y {}^f_p u_y b_{iy}}$$

where

$^m c_{ij}$ = the adjusted rectangular marriage rate for a male aged i marrying a female aged j

$^m_p u_i$ = the projected number of unmarried males aged i

$^f_p u_j$ = the projected number of unmarried females aged j

The factor multiplying b_{ij} is the ratio of (a) the fraction of marriages between males aged i and females aged j to all marriages involving either a male aged i or a female aged j in the projected population to (b) the same fraction in the rectangular population. The number of projected marriages between a male aged i and a female aged j, $_p n_{ij}$, is then calculated by the simple equation:

$$_p n_{ij} = {}^m c_{ij} \; {}^m_p u_i$$

Similar adjusted rates could be developed for females, but this is unnecessary, since

$$ {}^f c_{ij} {}_p^f u_j = {}^m c_{ij} {}_p^m u_i = {}_p n_{ij} $$

This is a very important property of the concept of rectangular rates developed by Schoen.

B. Assumptions

Starting Population

The starting population for the projections was the estimated population in the
Social Security Area as of July 1, 1977 by single years of age, by sex, and by
marital status. The components of the Social Security Area and the estimated
population of each component (in thousands) are as follows:

Residents of the 50 states and D.C. (including armed forces overseas)	216,880
Adjustment for net census undercount	5,499
Residents of Puerto Rico	3,316
Residents of American Samoa, Guam, and the Virgin Islands	235
Federal civilian employees and dependents overseas	400
Crew members of merchant vessels	28
Other citizens overseas	437
Total	226,795

The number of residents of the 50 states and D.C. (including armed forces
overseas) and the adjustment for net undercount were estimated by the Bureau
of the Census by sex and by single years of age up to age 85. The age distri-
bution of those aged 85 and over was assumed to be the same as that in the
population enrolled under the Medicare program as of January 1, 1977. The
number of residents of Puerto Rico, American Samoa, Guam, and the Virgin Islands
was estimated by single years of age from data supplied by the Bureau of the
Census. The number of federal civilian employees overseas and their dependents
and of dependents of the armed forces overseas was estimated from data supplied
by the State Department and the Office of Personnel Management. The number of
crew members of merchant vessels was obtained from the Maritime Administration.
The number of other citizens overseas covered by Social Security was estimated
from data supplied by the State Department. The overlap among the components
is believed to be small and has been ignored.

The population by marital status (never married, currently married, currently
widowed, or currently divorced) was estimated from data supplied by the
Bureau of the Census. The married population was estimated by single years
of age of the husband crossed by single years of age of the wife. The percentage
married by age group and sex was obtained from the March 1977 Current Population
Survey (CPS). These percentages were multiplied by the starting population to
obtain an estimate of the starting married population by age group and sex. The
married population by single years of age was derived by Karup-King interpolation.
A distribution of the married population by age of husband crossed with age of
wife was estimated from data in the 1970 census. This distribution was modified
by an iterative proration method until it very nearly matched the estimated 1977
starting married population by age and sex.

- 5 -

The total unmarried starting population was calculated by subtracting the married starting population from the total starting population by age group and sex. The result was then distributed by never married (hereafter denoted single), widowed, and divorced based on percentages from the 1977 CPS. Finally, values by single years of age were estimated by Karup-King interpolation. Tables 1 show the starting population in the Social Security Area by age group, sex, and marital status. Table 2 shows the starting married population by age group of husband and age group differential between husband and wife.

Fertility, Mortality, and Net Immigration

The total fertility rate (which is the sum of the age-specific central birth rates) declined steadily from a peak of 3.7 children per woman in 1957 to a low point of 1.7 children per woman in 1976. Since that time it has fluctuated between 1.7 and 1.8. The total fertility rate was assumed to ultimately exceed 1.7, but not to return to the high levels observed in the past. The total fertility rate was projected to increase from 1.8 children per woman in 1977 to an ultimate rate of 2.1 children per woman in 2005.

Mortality was projected by age, sex, and cause of death. Ultimate annual rates of improvement by cause of death were assumed to be reached by the year 2000, with more rapid improvement assumed between 1977 and 2000. These assumptions resulted in age-adjusted central death rates which decline from 10.70 per thousand for males and 6.13 per thousand for females in 1977 to 6.62 and 3.31 per thousand for males and females, respectively, in 2080.

Net immigration was assumed to be 400,000 survivors at the end of each year, roughly the level experienced since the enactment of the Immigration Act of 1965.

These assumptions are the alternative II assumptions for the 1980 Trustees Report. They are described more fully in Actuarial Study No. 82.

Marriages

The observed marriage rates for this study were calculated from data provided by NCHS on marriages by age of groom crossed with age of bride during 1977 in the states belonging to the Marriage Registration Area (MRA) and from the unmarried starting population in the Social Security Area. The MRA includes 41 states and D.C., and accounts for about 80 percent of the estimated marriages in the United States and about 78 percent of the marriages in the Social Security Area. Rectangular marriage rates were derived from age 15 through 74 and were adjusted to take into account the marriages in the Social Security area but not in the MRA and also the recent trend in the number of marriages. The resulting rates, summed into 5 year age groups, are shown in table 4.

Although the rectangular rates were adjusted every year in the projection period to reflect the change in the age-sex composition of the unmarried population, trends were not projected in the rectangular marriage rates themselves. This assumption does not imply, however, that the gross marriage rates will remain constant.

Divorces

In theory, rectangular divorce rates can be developed in a manner similar to rectangular marriage rates. However, less is gained by the use of rectangular divorce rates, because the decision of a particular married couple to become divorced has little to do with the number of married couples in the population with nearly the same ages, i.e. there is no "divorce market" analogous to a "marriage market." Also desirable in theory, would be divorce rates by age of husband crossed with age of wife, but in practice these divorce rates are difficult to develop because the available data are scarce and of low quality. Information about characteristics of divorces, such as age of husband and age of wife at the time of decree, is available only from States that participate in the Divorce Registration Area (DRA). Since 1971, the DRA has included only 29 states, and the non-response rate to questions of age is roughly 1/6.

For this projection, a simplified approach that fits in well with recent trends was used. The divorce rate per 1,000 married women has increased from 9.2 in 1960 to just over 22 in 1979. A constant divorce rate of 23 per 1,000 married women was used to estimate future divorces. The distribution of divorces by the age of the wife was assumed to remain the same as it was in the DRA in calendar year 1976. This distribution is shown in table 5.

C. Methods

Death Rates by Marital Status

Stationary population death rates (i.e., the probabilities that persons between two integral ages will die within one year) were derived by single years of age, sex, and marital status for each year 1978 through 2080 from the mortality projection associated with Actuarial Study No. 82. The relative value of the death rates by marital status was determined from data for white persons in the United States for 1959-61.[3/] Table 3 shows stationary population death rates derived for 1977 for selected ages, by sex and marital status.

Married Persons

The starting married population was represented by a married couples grid showing the number of married couples by age of husband crossed with age of wife. Joint-life probabilities were used to project the number of married couples surviving intact for one year. Individual-life probabilities were used to project the number of surviving males and surviving females separately. The number of newly created widowers was taken as the excess of the surviving males over the surviving married males. Similarly, the number of newly created widows was taken as the excess of the surviving females over the surviving married females.

The number of new divorces was taken as 2.3% of the surviving married couples. These divorces were then assumed to have the same distribution by age of wife as did the divorces in the DRA in calendar year 1976. For any given age of wife, the distribution of divorces by age of husband was assumed to be the same as the distribution of surviving marriages exposed to divorce.

Non-married Persons

The surviving non-married persons were projected by applying death rates by age, sex, and marital status. To calculate the total number of marriages during the year by age of husband crossed with age of wife, the adjusted rectangular marriage rates were applied to the total surviving unmarried population. The total number of males marrying at each age was obtained by summation across all ages of females. Likewise, the total number of females marrying at each age was obtained by summation across all ages of males.

To determine the distribution of the total marriages by previous marital status, marriage rates were developed for each sex separately by age and marital status (i.e., rates for the never married, the currently divorced, and the currently widowed). Data from the Marriage Registration Area in 1976 supplied by NCHS was used to calculate these rates which were applied to the unmarried population by marital status to obtain a distribution of the total marriages for each age and sex by previous marital status. Finally, the total marriages calculated with the rectangular rates for each age and sex were distributed by previous marital status according to this distribution.

[3/] Mortimer Spiegelman, Introduction to Demography, Harvard University Press, 1973 p. 91

Migration and Births

After the survivors from the population at the beginning of the year were
calculated and all of their changes in marital status were determined, the
estimated net migration and births were added to the population. Net
surviving migration was added to the unmarried population by age and sex.
The distribution by marital status was based on the resident population at
the end of the year.

Births were calculated from age-specific fertility rates applied to the
total female population. Different rates were not applied by marital status,
thus assuring consistency with the projections in Actuarial Study No. 82.

D. Results

Table 6 gives past and projected marriages for selected years. The total number of marriages are estimated to increase steadily throughout the projection period. A particularly rapid increase in marriages is projected for the late 1970's and early 1980's resulting from the baby boom generation attaining the prime marrying ages of 18-28 during this period. Table 6 also shows that the use of constant rectangular marriage rates produces changes through time in the various crude marriage rates.

The rate of marriage per 1,000 total population and the rate per 1,000 unmarried women 15 years of age or over generally decline throughout the projection period. This is a result of the general aging of the population, which causes the proportion of the population at the younger ages, where marriage is more prevalent, to decrease. The annual rate of marriage per 1,000 unmarried women aged 15-44 is projected to increase from 106 in 1980 to almost 120 in 1990. It stays at about that level until 2000 and then increases again to about 123.5 in 2010 and later. The increase in this rate during the 1980's reflects both the movement of the baby boom generation into the lower end of the age interval 15-44, where marriage rates are higher, and also the increase in the projected numbers of divorces, which tends to keep the average age of the unmarried population lower. After the year 2000, the baby boom generation starts moving out of the 15-44 age group, resulting in faster deceleration in the increase in the denominator of the marriage rate than in the numerator.

Table 7 gives the past and projected divorces and annulments and the rate per 1,000 total population and per 1,000 married women. The number of divorces increases steadily from 1.1 million in 1980 to 1.4 million in 2010 and remains fairly constant thereafter. This generally follows the trend in the total number of married people. The divorce rate per 1,000 total population decreases because the proportion of the population which is married decreases. This is a result of the general aging of the population and of the high divorce rates themselves.

Table 8 shows the projected number of widowhoods in the Social Security Area by age group and sex for selected years. The total number of widowhoods is projected to increase steadily from 884,000 during the year ending July 1, 1980 to 1,552,000 during the year ending July 1, 2040, because the population is increasing during these years. The number of widowhoods then declines slightly to 1,505,000 during the year ending July 1, 2060, because the proportion of the population at the older ages, where widowhood is more likely, decreases during this period as the baby boom generation leaves the population.

No noticeable trend exists in the number of widowhoods within any age group except for the steadily increasing number in the age group 90 and over. The number of widowhoods is a function of the number of married persons and of mortality rates. The decreasing mortality rates used in the projection would result in a decreasing number of widowhoods within each age group if the number of married persons in each age group remained constant. The number of married persons in the age group 50 and over, where most of the widowhoods occur, is projected to fluctuate around a generally increasing path. This unsteady rate of growth is the result of the interactions of changing fertility rates, mortality rates, marriage rates, and divorce rates.

Tables 9 give the projected population in the Social Security Area by age group, sex, and marital status for selected years. The proportion of the population which is single is projected to decrease from 42 percent in 1980 to 36 percent in 2060, while the proportions married, widowed, and divorced are all projected to increase. The proportion married increases slightly, from 47 percent in 1980 to 48 percent in 2060, while the proportion widowed increases from 6 percent to 7 percent, and the proportion divorced increases from 5 percent to 9 percent. The two factors that have the greatest effect on these proportions are (1) the decreasing death rates, which results in an increasing proportion of the population at the older ages, and (2) the increasing prevalence of divorce, which is the result of using the current high incidence of divorce in the projection.

Although for the total population the proportion single goes down, and the proportion widowed goes up with time, for most age groups the reverse is true. For widows this is because decreasing probabilities of death result in a lower proportion of widows at any given age, but a higher proportion in total as the aged (where widows are more prevalent) become a higher proportion of the total population. The increasing proportion of singles at any particular age is because the unmarried population is consisting of more divorced persons, resulting in fewer marriages among never married persons. However, since the population is aging, the proportion of the population at the young ages where singles are more prevalent is decreasing.

The proportion of the population that is married increases slightly through time, the net result of a decreasing proportion of the population being married at the younger ages (because of the increasing proportion divorced) and of an increasing proportion of the population being married at the older ages (because of the decreasing proportion widowed).

The proportion of the population that is divorced is projected to increase for every age group, but particularly so for the older age groups.

Total	6,581	10,843	28,713	62,052	110,676	116,394	40,835	12,439	4,513	393,045

* Rectangular total marriage rates per 100,000 represent the expected number of unmarried persons for each sex separately marrying within one year in a population with exactly 100,000 unmarried persons at each age for each sex. Unmarried persons specifically include the currently widowed or divorced, as well as the never married.

** For example, there were 17,243 husbands age 35-39 married to wives in in the age group 30-34.

Table 5. Divorces and Annulments by Age of Wife at Time of Decree,
Calendar Year 1976*

| Age of | Divorces and Annulments | |
Wife	Number	As Ratio to Total
Under 20	22,535	.0411
20-24	122,824	.2242
25-29	137,313	.2506
30-34	91,398	.1668
35-39	61,223	.1118
40-44	43,047	.0786
45-49	30,429	.0555
50-54	19,186	.0350
55-59	10,623	.0194
60-64	5,132	.0094
65+	4,137	.0076
Total	547,847	1.0000

* The data for this table were supplied by the National Center
for Health Statistics. The data are limited to those divorces
and annulments in the Divorce Registration Area for which the
age of the wife was stated.

Table 6. Past and Projected Marriages for Selected Years

Year*	Estimated Number of Marriages** (in thousands)	Rate of Marriage per 1,000-		
		Total Population	Unmarried Women 15 years or over	Unmarried Women 15-44
1925	1,188	10.3	----	-----
1930	1,127	9.2	----	-----
1935	1,327	10.4	----	-----
1940	1,596	12.1	82.8	122.4
1945	1,613	12.2	83.6	138.2
1950	1,667	11.1	90.2	166.4
1955	1,531	9.3	80.9	161.1
1960	1,523	8.5	73.5	148.0
1965	1,800	9.3	75.0	144.3
1970	2,159	10.6	76.5	140.2
1975	2,153	10.1	66.9	118.5
1976	2,155	10.0	65.2	113.4
1977	2,178	10.1	63.6	109.8
1980	2,404	10.3	62.6	106.4
1985	2,685	11.0	65.6	114.5
1990	2,744	10.8	64.9	119.6
1995	2,718	10.3	62.0	120.8
2000	2,763	10.1	59.7	120.0
2010	2,968	10.2	58.7	123.5
2020	3,029	9.9	56.4	125.1
2030	3,093	9.7	53.6	123.6
2040	3,154	9.6	52.0	124.3
2050	3,217	9.6	51.7	123.9

* Historical figures are for calendar years, while the projected figures are for the 12-month period ending on July 1 of the year shown.

** Historical figures are on marriages occurring within the United States, i.e. the 50 States and the District of Columbia, whereas the projected figures are on marriages occurring within the Social Security Area. During 1975, there were 33,795 marriages in Puerto Rico and the Virgin Islands. The number of marriages abroad by persons in the Social Security Area is unknown. It is believed that over 98% of the marriages in the Social Security Area occur within the 50 States and D.C. The difference in the rates of marriage between the United States and the Social Security Area is negligible.

Table 7. Past and Projected Divorces and Annulments for Selected Years

Year*	Estimated Number of Divorces and Annulments** (in thousands)	Rate of Divorce or Annulment per 1,000	
		Total Population	Married Women
